| 12    | <b>ReTuningEvent.</b> Read-only. Reset: 0. 1=Re-tuning should be performed.                                                                                                                                                                                                                                                                                                                                                          |
| 11:9  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 8     | <b>Sdio.</b> Read; Write-1-to-clear. Reset: 0. SDIO Card Interrupt. Writing 1 to this register does not clear this bit. To clear this bit, interrupt factor of SDIO cards should be cleared. The value of this bit is latched internally as long as the Card Interrupt bit in the Normal Interrupt Status Enable register ( <a href="#">SDHC0x34[SdioMask]</a> )==1.                                                                 |
| 7     | <b>CardRem.</b> Read; Write-1-to-clear. Reset: 0. Card Removal.                                                                                                                                                                                                                                                                                                                                                                      |
| 6     | <b>CardIns.</b> Read; Write-1-to-clear. Reset: 0. Card Insertion.                                                                                                                                                                                                                                                                                                                                                                    |
| 5     | <b>BufRdRdy.</b> Read; Write-1-to-clear. Reset: 0. Buffer Read Ready. In the case where <a href="#">SDHC0x0C[AutoCmdEn]</a> ==01b and last block has been transferred, Auto CMD12 will be issued prior to this bit being set to 1. Clearing this bit should be done before buffer reading, because SD controller has dual buffer and the next Buffer Read Ready interrupt may occur immediately.                                     |
| 4     | <b>BufWrRdy.</b> Read; Write-1-to-clear. Reset: 0. Buffer Write Ready. Clearing this bit should be done before buffer writing, because the SD controller has dual buffer and the next Buffer Write Ready interrupt may occur immediately.                                                                                                                                                                                            |
| 3     | <b>DmaEvt.</b> Read; Write-1-to-clear. Reset: 0. DMA Interrupt. It is set when internal counter reaches the value designated by Host DMA Buffer Boundary ( <a href="#">SDHC0x04[DmaBufBndry]</a> ). It should be cleared by Host Driver after System Address Register ( <a href="#">SDHC0x00</a> ) is updated.                                                                                                                       |
| 2     | <b>BlockGapEvt.</b> Read; Write-1-to-clear. Reset: 0. Block Gap Event. It indicates the timing of next block gap, which was requested by <a href="#">SDHC0x28[BgStopReq]</a> . In case of write transaction, this interrupt will be generated before busy completion.                                                                                                                                                                |
| 1     | <b>DatDone.</b> Read; Write-1-to-clear. Reset: 0. Data Transfer Complete. Indicates the timing for completion of data transaction, which includes the completion at the block gap by <a href="#">SDHC0x28[BgStopReq]</a> . When some errors are detected during data transaction, this bit will not be set. In the case where <a href="#">SDHC0x0C[AutoCmdEn]</a> ==01b, Auto CMD12 will be issued prior to this bit being set to 1. |
| 0     | <b>CmdDone: cmdDone (r).</b> Read-write. Reset: 0. Command Complete. The end bit of the command response is received. In the case of commands with no response, the end of the command.                                                                                                                                                                                                                                              |

This bit controls the device's response to parity errors. 1=The device must take its normal action when a parity error is detected. 0=The device must ignore any parity errors that it detects and continue normal operation. |
| 5 | <b>VGAPaletteSnoop: VGA Palette Snoop.</b> Value: 0. This bit does not apply to this module.                                                                                                                                                                                                           |
| 4 | <b>MemoryWriteInvalidateEnable: Memory Write and Invalidate Enable.</b> Value: 0. This module does not generate Memory Write and Invalidate commands.                                                                                                                                                  |
| 3 | <b>SpecialCycle: Special Cycle.</b> Value: 0. This module does not respond to special cycles.                                                                                                                                                                                                          |
| 2 | <b>BusMaster: Bus Master.</b> Value: 0. ACPI/SMBus does not have a PCI master.                                                                                                                                                                                                                         |
| 1 | <b>MemorySpace: Memory Space.</b> Read-write. Reset: 1. 1=Enable the device to respond to memory space accesses.                                                                                                                                                                                       |
| 0 | <b>IOSpace: IO Space.</b> Read-write. Reset: 1. 1=Enable the device to respond to IO space accesses.                                                                                                                                                                                                   |

**D14F0x08 Revision ID/Class Code**

| Bits | Description                                                                |
|------|----------------------------------------------------------------------------|
| 31:8 | <b>ClassCode: Class Code.</b> Value: C0500h. Specifies a SMBus controller. |
| 7:0  | <b>RevisionID: Revision ID.</b> Value: 42h.                                |

**D14F0x0C Cache Line Size**

| Bits  | Description                                                                                                                                                                            |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>Bist.</b> Value: 0. The module has no built-in-self-test and so this is always 0.                                                                                                   |
| 23:16 | <b>HeaderType: Header Type.</b> Value: 80h. This device is a multifunction device.                                                                                                     |
| 15:8  | <b>LatencyTimer: Latency Timer.</b> Value: 0. This register specifies the value of the Latency Timer. This is not used in this module and so it is always 0.                           |
| 7:0   | <b>CacheLineSize: Cache Line Size.</b> Value: 0. Specifies the system cache line size. 0=Device does not use Memory Write and Invalidate commands and CacheLineSize is not applicable. |

**D14F0x10 Base Address 0**

| Bits | Description                                    |
|------|------------------------------------------------|
| 31:0 | <b>BaseAddress0: Base Address 0.</b> Value: 0. |

**D14F0x14 Base Address 1**

| Bits | Description                                    |
|------|------------------------------------------------|
| 31:0 | <b>BaseAddress1: Base Address 1.</b> Value: 0. |

**D14F0x18 Base Address 2**

| Bits | Description                                    |
|------|------------------------------------------------|
| 31:0 | <b>BaseAddress2: Base Address 2.</b> Value: 0. |

**D14F0x1C Base Address 3**

| Bits | Description                                    |
|------|------------------------------------------------|
| 31:0 | <b>BaseAddress3: Base Address 3.</b> Value: 0. |

**D14F0x20 Base Address 4**

| Bits | Description                                    |
|------|------------------------------------------------|
| 31:0 | <b>BaseAddress4: Base Address 4.</b> Value: 0. |

**D14F0x24 Base Address 5**

| Bits | Description                                    |
|------|------------------------------------------------|
| 31:0 | <b>BaseAddress5: Base Address 5.</b> Value: 0. |

**D14F0x28 Cardbus CIS Pointer**

| Bits | Description                                              |
|------|----------------------------------------------------------|
| 31:0 | <b>CardbusCISPointer: Cardbus CIS Pointer.</b> Value: 0. |

**D14F0x2C Subsystem Vendor ID**

| Bits  | Description                                                              |
|-------|--------------------------------------------------------------------------|
| 31:16 | <b>SubsystemID: Subsystem ID.</b> Write-once. Reset: 780Bh.              |
| 15:0  | <b>SubsystemVendorID: Subsystem Vendor ID.</b> Write-once. Reset: 1022h. |

**D14F0x30 Expansion ROM Base Address**

| Bits | Description                                                           |
|------|-----------------------------------------------------------------------|
| 31:8 | Reserved.                                                             |
| 7:0  | <b>ExpansionROMBaseAddress: Expansion ROM Base Address.</b> Value: 0. |

**D14F0x34 Capability Pointer**

| Bits | Description                                             |
|------|---------------------------------------------------------|
| 31:8 | Reserved.                                               |
| 7:0  | <b>CapabilityPointer: Capability Pointer.</b> Value: 0. |

**D14F0x3C Interrupt Line**

| Bits  | Description                                                                                 |
|-------|---------------------------------------------------------------------------------------------|
| 31:24 | <b>MaxLat.</b> Value: 0. Device has no requirements for the setting.                        |
| 23:16 | <b>MinGnt.</b> Value: 0. Device has no requirements for the setting.                        |
| 15:8  | <b>InterruptPin: Interrupt Pin.</b> Value: 0. 0=This module does not generate interrupts.   |
| 7:0   | <b>InterruptLine: Interrupt Line.</b> Value: 0. 0=This module does not generate interrupts. |

**3.26.7.2 ASF (Alert Standard Format) Registers**

ASF register space is accessed through two methods:

- IO access through ASF IO base address:
  - Program the base address of ASF IO space through [PMx00\[SmbusAsfIoBase\]](#).
  - Enable ASF IO decoding through [PMx00\[SmbusAsfIoEn\]](#).
- Direct memory mapped access through the AcpiMmio region. The ASF registers range from FED8\_0000h+900h to FED8\_0000h+9FFh. See [PMx04\[MmioEn\]](#).

**ASFx00 HostStatus**

| Bits | Description                                                                                                                                           |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>LastByte.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 0=Last byte has not received. 1=Last byte has received.                           |
| 6:5  | Reserved.                                                                                                                                             |
| 4    | <b>PECError.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 0=No CRC error. 1=CRC error happened.                                             |
| 3    | <b>BusCollision.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 0=No bus collision. 1=Bus collision.                                          |
| 2    | <b>DevError.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 0=Slave device behaves correctly. 1=No ACK or slave device responses incorrectly. |
| 1    | <b>Intr.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 1=Termination of a command. Whenever [HostBusy] is cleared, this bit is set.          |
| 0    | <b>HostBusy.</b> Read-only; updated-by-hardware. Reset: 0. This bit reports the status of the ASF host. 0=SM bus host is idle. 1=SM bus host is busy. |

**ASFx02 HostControl**

| Bits | Description                                                                                                                              |
|------|------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>PECEnable.</b> Read-write. Reset: 0. 0=PEC disable. 1=PEC enable. Enable CRC checking when ASF HC presents as SM master and SM slave. |

| 6    | <b>Start.</b> Write-1-only; Read. Reset: 0. 1=Writing 1 to initiate the command. Always read back as 0.                                                                                                                                                                                                                                                                                                                                                              |      |            |      |       |      |      |      |           |      |           |      |              |      |       |      |                                     |      |          |

| 1 | <b>SlaveIntrListenEn.</b> Read-write. Reset: 0. 1=Allow ASF slave to generate slave interrupt when the address of received packet is the same as the one specified in ListenAdr register <a href="#">ASFx09 [ListenAdr]</a> . |
| 0 | Reserved.                                                                                                                                                                                                                     |

### ASFx16 DelayMasterTimer

| Bits | Description                                                                                                                                          |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>FairArbTimer.</b> Read-write. Reset: 04h. Specify how long ASF master has to wait before submitting next packet. Wait time = FairArbTimer * 2 us. |

### 3.26.7.3 SMBus Registers

SMBus register space is accessed through two methods:

- IO access through SMBus IO base address:
  - Program the base address of SMBus IO space through [PMx00\[SmbusAsfIoBase\]](#).
  - Enable SMBus IO decoding through [PMx00\[SmbusAsfIoEn\]](#).
- Direct memory mapped access through the AcpiMmio region. The SMBus registers range from FED8\_0000h+A00h to FED8\_0000h+AFFh. See [PMx04\[MmioEn\]](#).

### SMBUSx00 SMBusStatus

| Bits | Description                                                                                                                                                                                                                                        |

**SMBUSx03 SMBusHostCmd**

| Bits | Description                                                                                                                         |
|------|-------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusHostCmd.</b> Read-write. Reset: 0. This field contains the data transmitted in the command field of SMBus host transaction. |

**SMBUSx04 SMBusAddress**

| Bits | Description                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------|
| 7:1  | <b>SMBusAddr.</b> Read-write. Reset: 0. This field contains the 7-bit address of the target slave device. |
| 0    | <b>SMBusRdWr.</b> Read-write. Reset: 0. 0=Execute a Write command. 1=Execute a Read command.              |

**SMBUSx05 SMBusData0**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusData0</b> . Read-write. Reset: 0. This register should be programmed with a value to be transmitted in the data 0 field of an SMBus host interface transaction. For block write commands, the count of the memory should be stored in this field. The value of this register is loaded into the block transfer count field. A valid value for block command count is between 1 and 32. For block reads, count received from SMBus device is stored here. |

**SMBUSx06 SMBusData1**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusData1</b> . Read-write. Reset: 0. This register should be programmed with a value to be transmitted in the data 1 field of an SMBus host interface transaction. When $(\text{SMBUSx14}[\text{SMBusPoll2Byte}] == 1) \ \& \ ((\text{SMBUSx02}[\text{SMBusProtocol}] == 001b) \mid (\text{SMBUSx02}[\text{SMBusProtocol}] == 010b))$ , this register is used as the data field in the second transaction. |

**SMBUSx07 SMBusBlockData**

| Bits | Description                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusBlockData</b> . Read-write. Reset: 0. This register is used to transfer data into or out of the block data storage array. |

**SMBUSx08 SMBusSlaveControl**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>ClrEcSemaphore</b> . Read; Write-1-only; cleared-by-hardware. Reset: 0. Write 1 to clear EcSemaphore bit.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 6    | <b>EcSemaphore</b> . Read; Write-1-only; cleared-by-hardware. Reset: 0. This bit can only be set when HostSemaphore is clear. Reading returns the value of this bit.                                                                                                                                                                                                                                                                                                                                                                    |
| 5    | <b>ClrHostSemaphore</b> . Read; Write-1-only; cleared-by-hardware. Reset: 0. Write 1 to clear HostSemaphore bit.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 4    | <b>HostSemaphore</b> . Read; Write-1-only; cleared-by-hardware. Reset: 0. HostSemaphore and EcSemaphore are meant to be used as software semaphore between the host and embedded controller. When both host and IMC want to use the same resource, they can write to these semaphore bits first, followed by a read. If the read returns a 1 in the semaphore bit, it means it has established the semaphore first. Write 1 to set this bit. This bit can only be set when EcSemaphore is clear. Reading returns the value of this bit. |
| 3    | <b>SMBusAlertEnable</b> . Read-only. Reset: 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 2    | <b>SMBusShadow2En</b> . Read-write. Reset: 0. Enable the generation of an interrupt or resume event upon an external SMBus master generating a transaction with an address that matches the SMBus Shadow 2 register.                                                                                                                                                                                                                                                                                                                    |

|   |                                                                                                                                                                                                                                                                                                                                        |
|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | <b>SMBusShadow1En.</b> Read-write. Reset: 0. Enable the generation of an interrupt or resume event upon an external SMBus master generating a transaction with an address that matches the SMBus Shadow 1 register.                                                                                                                    |
| 0 | <b>SlaveEnable.</b> Read-write. Reset: 0. Enable the generation of an interrupt or resume event upon an external SMBus master generating a transaction with an address that matches the host controller slave port of 10h, a command field that matches the SMBus slave control register, and a match of corresponding enabled events. |

**SMBUSx09 SMBusShadowCmd**

| Bits | Description                                                                                                                                                                                                                            |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusShadowCmd.</b> Read-write. Reset: 0. This field contains the command value that was received during an external SMBus master access whose address field matched the host slave address (10h) or one of the slave shadow ports. |

**SMBUSx0A SMBusSlaveEvent**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | <b>SMBusSlaveEvent.</b> Read-write. Reset: 0. This field contains data bits used to compare against incoming data to the SMBus Slave Data register ( <b>SMBUSx0C</b> ). When a bit in this register is 1 and a corresponding bit in SMBus slave's register is set, then an interrupt or resume event is generated if the command value matches the value in the SMBus slave's control register and the access was to SMBus host address 10h. |

**SMBUSx0C SlaveData**

| Bits | Description                                                                                                                                                                                                                                                        |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | <b>SlaveData.</b> Read-write. Reset: 0. This field contains the data value which was transmitted during an external SMBus master access whose address field matched one of the slave shadow port addresses or the SMBus host controller slave port address of 10h. |

**SMBUSx0E SMBusTiming**

| Bits | Description                                                                                                                                                                     |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusTiming.</b> Read-write. Reset: B0h. This register controls the frequency on the SMBus. The formula to calculate the frequency is: Frequency = 66 MHz/(SMBusTiming * 4). |

**SMBUSx10 I2CbusConfig**

| Bits | Description                                                          |
|------|----------------------------------------------------------------------|
| 7:4  | <b>I2CRevision.</b> Read-write. Reset: 0. SMBus controller revision. |
| 3:1  | Reserved.                                                            |
| 0    | <b>I2CbusInterrupt.</b> Read-write. Reset: 0. 0=SMI#. 1=IRQ.         |

**SMBUSx11 I2CCommand**

| Bits | Description                                                                                                                                                                               |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>I2Ccommand</b> . Read-write. Reset: 0. I2C Host Slave Command. This value specifies the command value to be matched for I2C master accesses to the I2Ccontroller host slave interface. |

**SMBUSx12 I2CShadow1**

| Bits | Description                                                                                                                                                                                      |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:1  | <b>I2CslaveAddr1</b> . Read-write. Reset: 0. SMBus Slave Address for shadow port 1. This value specifies the address used to match against incoming I2C addresses for Shadow port 1.             |
| 0    | <b>ReadWriteShadowPort1</b> . Read-write. Reset: 0. This bit must be programmed to 0 because the I2C slave controller only responds to Word Write Transactions. 0=Write command. 1=Read command. |

**SMBUSx13 I2Cshadow2**

| Bits | Description                                                                                                                                                                                 |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:1  | <b>I2CslaveAddr2</b> . Read-write. Reset: 0. SMBus slave address for shadow port 2. This value specifies the address used to match against incoming I2C addresses for Shadow port 2.        |
| 0    | <b>ReadWriteShadowPort2</b> . Read-write. Reset: 0. This bit must be programmed to 0 because I2C slave controller only responds to Word Write Transaction. 0=Write command. 1=Read command. |

**SMBUSx14 SMBusAutoPoll**

| Bits      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |      |            |      |                        |      |                       |      |                        |      |                        |           |                     |

| Bits | Description                                                                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusCounter</b> . Read-only; updated-by-hardware. This counter specifies the remaining time until the next read specified as (SMBusCounter*SMBUSx14[SMBusPollPeriod]/256) us. |

**SMBUSx16 SMBusStop**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:1 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 0    | <b>SMBusPausePoll</b> . Read-write. Reset: 0. This is to be used as a semaphore mechanism by software to stop the next polling. If software wants to use the SMBus for other purposes but the hardware has already been enabled (SMBUSx14[SMBusAutoPollEn]==1) to perform auto polling, software can halt the next polling by setting this bit to 1. If the halt is successful, this bit will return 1. If the HW has already started the polling operation at the same time software tries to set this bit, this bit will return 0. When the pending polling operation is finally complete, this bit will then get set. When this bit is set, polling counter will temporarily stop (not reset). It is now safe for software to access the SMBus. Upon completion, software must restore the previous command in the appropriate register prior to setting this bit. software should also clear this bit so the counter can resume counting. |

**SMBUSx17 SMBusHostCmd2**

| Bits | Description                                                                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusHostCmd2</b> . Read-write. Reset: 0. This field contains the data transmitted in the command field in the second command when (SMBUSx14[SMBusPoll2Byte]==1) and (SMBUSx02[SMBus-Protocol]==010b). |

### 3.26.8 IOAPIC Registers

IOAPIC configuration registers can be accessed at memory region from FEC0\_0000h to FEC0\_007Fh. Program [PMx00\[IoApicEn\]=1](#) to enable IOAPIC decoding.

#### IOAPICx00 IO Register Select Register

| Bits | Description                                                                                                                                                                                                  |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                    |
| 7:0  | <b>IndirectAddressOffset</b> . Read-write. Reset: 0. Indirect Address Offset to IO Window Register. It is used to determine which register is manipulated during an IO Window Register read/write operation. |

#### IOAPICx10 IO Window Register

| Bits | Description                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>IOWindow</b> . Read-write. Reset: 0. Mapped by <a href="#">IOAPICx00</a> to the designated indirect access register. |

#### IOAPICx10\_x00 IOAPIC ID Register

This register is not used in IOxAPIC PCI bus delivery mode.

| Bits  | Description                                         |
|-------|-----------------------------------------------------|
| 31:28 | Reserved.                                           |
| 27:24 | <b>ID</b> . Read-write. Reset: 0. IOAPIC device ID. |
| 23:0  | Reserved.                                           |

#### IOAPICx10\_x01 IOAPIC Version Register

| Bits  | Description                                                             |
|-------|-------------------------------------------------------------------------|
| 31:24 | Reserved.                                                               |
| 23:16 | <b>MaxRedirectionEntries</b> . Value: 17h. Indicates 24 entries [23:0]. |
| 15    | <b>PRQ</b> . Value: 1. IRQ pin assertion supported.                     |
| 14:8  | Reserved.                                                               |
| 7:0   | <b>Version</b> . Value: 21h. PCI 2.2 compliant.                         |

#### IOAPICx10\_x02 IOAPIC Arbitration Register

This register is not used in IOxAPIC PCI bus delivery mode.

| Bits  | Description                                                 |
|-------|-------------------------------------------------------------|
| 31:28 | Reserved.                                                   |
| 27:24 | <b>ArbitrationID: Arbitration ID</b> . Read-only. Reset: 0. |
| 23:0  | Reserved.                                                   |

**IOAPICx10\_x[3E:10:step2] Redirection Table Entry [23:0]**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                     |      |            |      |            |      |       |      |     |      |                 |      |      |      |         |      |          |      |          |      |        |

| Bits  | Description                                                                                                                                                                                                                         |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>DetectedParityError: Detected Parity Error.</b> Read; write-1-to-clear. Reset: 0. 1=The FCH detects a parity error.                                                                                                              |
| 30    | <b>SignaledSystemError: Signaled System Error.</b> Read; write-1-to-clear. Reset: 0. 1=The FCH detects a PCI address parity error.                                                                                                  |
| 29    | <b>ReceivedMasterAbort: Received Master Abort.</b> Read; write-1-to-clear. Reset: 0. 1=The FCH acts as a PCI master and aborts a PCI bus memory cycle.                                                                              |
| 28    | <b>ReceivedTargetAbort: Received Target Abort.</b> Read; write-1-to-clear. Reset: 0. 1=An FCH generated PCI cycle (the FCH is the PCI master) is aborted by a PCI target.                                                           |
| 27    | <b>SignaledTargetAbort: Signaled Target Abort.</b> Read; write-1-to-clear. Reset: 0. 1=The FCH signals target abort.                                                                                                                |
| 26:25 | <b>DeviceSelectTiming: Device Select Timing.</b> Value: 1. Indicates DEVSEL# timing when performing a positive decode. DEVSEL# is asserted to meet the medium timing.                                                               |
| 24    | <b>MasterDataParityError: Master Data Parity Error.</b> Read; write-1-to-clear. Reset: 0. 1=The FCH detects PERR# asserted while acting as PCI master regardless whether PERR# was driven by the FCH or not.                        |
| 23:21 | Reserved.                                                                                                                                                                                                                           |
| 20    | <b>CapabilitiesList: Capabilities List.</b> Read-only. Reset:0.                                                                                                                                                                     |
| 19:10 | Reserved.                                                                                                                                                                                                                           |
| 9     | <b>FastBack2BackEnable: Fast Back-to-Back Enable.</b> Value: 0.                                                                                                                                                                     |
| 8     | <b>SERREnable: SERR# Enable.</b> Read-only. Reset: 0. 1=The FCH asserts SERR# when it detects an address parity error. 0=SERR# is not asserted.                                                                                     |
| 7     | <b>SteppingControl: Stepping Control.</b> Value: 0.                                                                                                                                                                                 |
| 6     | <b>ParityErrorResponse: Parity Error Response.</b> Read-write. Reset: 0. PERR# (Response) Detection Enable bit. 1=The FCH asserts PERR# when it is the agent receiving data and it detects a parity error. 0=PERR# is not asserted. |
| 5     | <b>VGAPaletteSnoop: VGA Palette Snoop.</b> Value: 0.                                                                                                                                                                                |

|   |                                                                                                                                                                                              |
|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4 | <b>MemoryWriteAndInvalidateEnable: Memory Write and Invalidate Enable.</b> Value: 0.                                                                                                         |
| 3 | <b>SpecialCycles: Special Cycles.</b> Value: 1.                                                                                                                                              |
| 2 | <b>BusMaster: Bus Master.</b> Read-only. Reset: 1. 1=Bus master enabled.                                                                                                                     |
| 1 | <b>MemorySpace: Memory Space.</b> Value: 1.                                                                                                                                                  |
| 0 | <b>IOSpace: IO Space.</b> Read-only. Reset: 1. This bit controls access to the IO space registers. 1=Enable access to the legacy IDE ports, and PCI bus master IDE IO registers are enabled. |

**D14F3x08 Revision ID/Class Code**

| Bits | Description                                                                                  |
|------|----------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode: Class Code.</b> Read-only. Reset: 60100h. Indicates an ISA bridge.             |
| 7:0  | <b>RevisionID: Revision ID.</b> Value: 11h. Indicates the revision level of the chip design. |

**D14F3x0C Cache Line Size**

| Bits  | Description                                                                                                                                                                                              |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>Bist.</b> Read-only. Reset: 0. No BIST modes.                                                                                                                                                         |
| 23:16 | <b>HeaderType: Header Type.</b> Read-only. Reset: 80h. Identifies the type of the predefined header in the configuration space. The most significant bit is set to 1 to indicate a multifunction device. |
| 15:8  | <b>LatencyTimer: Latency Timer.</b> Read-only. Reset: 0. Specifies the value of the latency timer in units of PCICLKs.                                                                                   |
| 7:0   | <b>CacheLineSize: Cache Line Size.</b> Value: 0.                                                                                                                                                         |

**D14F3x10 Base Address Reg 0**

| Bits | Description                                                                                                                                                                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:5 | <b>BaseAddress0[31:5]: Base Address 0.</b> RAZ; write-only. Reset: 7F60000h. This register has an internal value used as base address for APIC memory space. Writing to the register changes its internal value. The default internal base address is FEC0_0000h. |
| 4:0  | <b>BaseAddress0[4:0].</b> Value: 0.                                                                                                                                                                                                                               |

**D14F3x2C Subsystem ID and Subsystem Vendor ID**

| Bits  | Description                                                                    |
|-------|--------------------------------------------------------------------------------|
| 31:16 | <b>SubsystemID: Subsystem ID.</b> Write-once; Read. Reset: 780Eh.              |
| 15:0  | <b>SubsystemVendorID: Subsystem Vendor ID.</b> Write-once; Read. Reset: 1022h. |

**D14F3x34 Capabilities Pointer**

| Bits | Description |
|------|-------------|
|------|-------------|

|      |                                                                       |
|------|-----------------------------------------------------------------------|
| 31:8 | Reserved.                                                             |
| 7:0  | <b>CapabilitiesPointer: Capabilities Pointer.</b> Read-only. Reset:0. |

**D14F3x40 PCI Control**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 7    | <b>IntegratedEcPresent.</b> Read-only; updated-by-hardware. Reset: 0. 1=IMC is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 6    | <b>EcSemaphore.</b> Read-write. Reset: 0. This bit is writable by IMC and read by BIOS. This is used as the software semaphore mechanism between BIOS and IMC to see who can access the common resource. IMC should read bit [BiosSemaphore] first to see if BIOS has taken ownership of the resource. If [BiosSemaphore] == 0, then IMC should write a 1 to this bit and then follow by a read to see if this bit is set. If this bit is set, it means IMC has successfully taken ownership of the resource. If this bit returns a 0 and [BiosSemaphore] returns a 1, then BIOS has taken ownership first. IMC should always clear this bit after it has completed its access to the resource.     |
| 5    | <b>BiosSemaphore.</b> Read-write. Reset: 0. This bit is writable by BIOS and read by the IMC. This is used as the software semaphore mechanism between BIOS and IMC to see who can access the common resource. BIOS should read bit [EcSemaphore] first to see if IMC has taken ownership of the resource. If [EcSemaphore] == 0, then BIOS should write a 1 to this bit and then follow by a read to see if this bit is set. If this bit is set, it means BIOS has successfully taken ownership of the resource. If this bit returns 0 and [EcSemaphore] returns a 1, then IMC has taken ownership first. Software should always clear this bit after it has completed its access to the resource. |

### D14F3x4C Memory Range

| Bits  | Description                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:12 | <b>BaseAddress: Base Address.</b> Read-write. Reset: 0. Specifies a 4K byte memory range from {Base Address, 000h} to {Base Address, FFFh}. The range is enabled by <a href="#">D14F3x48</a> [MemPortEnable]. |
| 11:0  | Reserved.                                                                                                                                                                                                     |

### D14F3x[5C,58,54,50] ROM Protect 3, 2, 1, 0

These registers specify different ROM ranges to be protected. [SPIx1D](#)[SpiProtectEn0] enables the protection ranges. The addresses are within the defined ROM range if:

{RomBase, 000\_0000\_0000b} <= address[31:0] < ({RomBase, 000\_0000\_0000b} + ((Range+1) << (RangeUnit ? 16 : 12) ) ).

For host, these registers can only be written once after hardware reset; Subsequent writes to it have no effect.

| Bits  | Description                                                                                                                                                                           |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:11 | <b>RomBase: ROM Base.</b> Read; write-once. Reset: 0.                                                                                                                                 |
| 10    | <b>WriteProtect: Write Protect.</b> Read; write-once. Reset: 0. 1=The memory range defined by this register is write-protected and writing to the range has no effect.                |
| 9     | <b>ReadProtect: Read Protect.</b> Read; write-once. Reset: 0. 1=The memory range defined by this register is read-protected and reading any location in the range returns FFFF_FFFFh. |
| 8     | <b>RangeUnit.</b> Read; write-once. Reset: 0. 0=4 KB. 1=64 KB.                                                                                                                        |
| 7:0   | <b>Range.</b> Read; write-once. Reset: 0. Specifies the protected range. The unit is defined by RangeUnit.                                                                            |

### D14F3x60 PCI Memory Address for LPC Target Cycles

This register contains the upper 16 bits of the start and end address of the LPC memory target range. The lower 16 bits of MemoryStartAddress are 0000h. The lower 16 bits of MemoryEndAddress are FFFFh. This range can be enabled or disabled using [D14F3x48](#)[MemoryRangePortEnable].

| Bits | Description |
|------|-------------|
|------|-------------|

|       |                                                                                                                                                         |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>MemoryEndAddress: Memory End Address.</b> Read-write. Reset: 0. Specifies the upper 16 bits of the end address of the LPC target memory range.       |
| 15:0  | <b>MemoryStartAddress: Memory Start Address.</b> Read-write. Reset: 0. Specifies the upper 16 bits of the start address of the LPC target memory range. |

#### D14F3x64 PCI IO base Address for Wide Generic Port

| Bits  | Description                                                                                                                                                                                                                                                                                                            |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>IOBaseAddress1: IO Base Address 1.</b> Read-write. Reset: 0. 16-bit PCI IO base address for wide generic IO port range. This function is enabled by <a href="#">D14F3x48</a> [WideIO1Enable]. If <a href="#">D14F3x74</a> [AlternativeWideIO1RangeEnable] == 1, the range is 16 bytes; else the range is 512 bytes. |
| 15:0  | <b>IOBaseAddress0: IO Base Address 0.</b> Read-write. Reset: 0. 16-bit PCI IO base address for wide generic IO port range. This function is enabled by <a href="#">D14F3x48</a> [WideIO0Enable]. If <a href="#">D14F3x74</a> [AlternativeWideIO0RangeEnable] == 1, the range is 16 bytes; else the range is 512 bytes. |

#### D14F3x68 ROM Address Range 1

This register contains the upper 16 bits of the start and end address of the ROM address range 1. The lower 16 bits of RomStartAddress1 are 0000h. The lower 16 bits of the RomEndAddress1 are FFFFh. This range can be enabled or disabled using [D14F3x48](#)[RomRange1PortEnable]. This register is used for both LPC and SPI flash.

| Bits  | Description                                                                                                                                               |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>RomEndAddress1: ROM End Address 1.</b> Read-write. Reset: 0Fh. Specifies the upper 16 bits of the end address of the ROM memory address range 1.       |
| 15:0  | <b>RomStartAddress1: ROM Start Address 1.</b> Read-write. Reset: 08h. Specifies the upper 16 bits of the start address of the ROM memory address range 1. |

#### D14F3x6C ROM Address Range 2

This register contains the upper 16 bits of the start and end address of the ROM address range 2. The lower 16 bits of RomStartAddress2 are 0000h. The lower 16 bits of RomEndAddress2 are FFFFh. This range can be enabled or disabled using [D14F3x48](#)[RomRange2PortEnable]. This register is used for both LPC and SPI flash.

| Bits  | Description                                                                                                                                                 |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>RomEndAddress2: ROM End Address 2.</b> Read-write. Reset: FFFFh. Specifies the upper 16 bits of the end address of the ROM memory address range 2.       |
| 15:0  | <b>RomStartAddress2: ROM Start Address 2.</b> Read-write. Reset: FFF8h. Specifies the upper 16 bits of the start address of the ROM memory address range 2. |

#### D14F3x74 Alternative Wide IO Range Enable

| Bits | Description |
|------|-------------|
| 31:4 | Reserved.   |

|   |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3 | <b>AlternativeWideIO2RangeEnable: Alternative Wide IO 2 Range Enable.</b> Read-write. Reset: 0. This bit is similar to bit [AlternativeWideIO0RangeEnable], but it applies to the IO range defined by <a href="#">D14F3x90</a> [IOBaseAddress2]. See bit [AlternativeWideIO0RangeEnable] for detailed description.                                                                                                                                   |
| 2 | <b>AlternativeWideIO1RangeEnable: Alternative Wide IO 1 Range Enable.</b> Read-write. Reset: 0. This bit is similar to bit [AlternativeWideIO0RangeEnable], but it applies to the IO range defined by <a href="#">D14F3x64</a> [IOBaseAddress1]. See bit [AlternativeWideIO0RangeEnable] for detailed description.                                                                                                                                   |
| 1 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 0 | <b>AlternativeWideIO0RangeEnable: Alternative Wide IO 0 Range Enable.</b> Read-write. Reset: 0. 0=Wide IO range defined by <a href="#">D14F3x64</a> [IOBaseAddress0] is 512 bytes. 1=The range is 16 bytes. To use this feature, address in <a href="#">D14F3x64</a> [IOBaseAddress0] must be aligned to 16 bytes, i.e., bits[3:0] must be 0. If the address is not aligned to 16 bytes, the IO range is from address[15:0] to {address[15:4], 0xF}. |

### D14F3x78 Miscellaneous Control Bits

| Bits  | Description                                                                                                                                                                                                                       |

#### 3.26.9.2 SPI Registers

SPI configuration registers are accessed through SPI base address specified by [D14F3xA0](#). Software can communicate with the SPI ROM through the default memory or alternate program method:

- Memory access to the BIOS ROM address space is automatically handled by the hardware. The SPI ROM controller translates the memory address onto the SPI bus and accesses the SPI ROM data. Any other commands besides memory read or memory write to the SPI ROM need to go through the alternate program method.
- In alternate program method, software needs to program the SpiOpCode, SpiAddress, TxByteCount, RxByteCount, put the data into the transmit FIFO, and then execute the command. The hardware communicates with the SPI ROM using these parameters. This alternate method basically allows software to issue any flash vendor specific commands such as ERASE and STATUS.

| 16    | <b>ExecuteOpCode</b> . Write-1-only; cleared-by-hardware. Reset: 0. Write 1 to execute the transaction in the alternate program registers. This bit returns to 0 when the transaction is complete. If the command is an illegal command, the bit cannot be set and thereby cannot execute.                                                                                                                                                                                                                                                                                                        |      |            |      |                         |      |          |      |                 |      |                 |      |                 |      |                 |      |                         |      |           |

This field is used to compare against the opcode sent out by the MAC. If <b>SPIx0C</b> [TrackMacLockEn]==1, the controller unlocks the SPI bus for the MAC. In other words, access by the CPU is allowed again.                                                                                                                                         |
| 15:8  | <b>MacLockCmd1.</b> IF ( <b>SPIx00</b> [SpiAccessMacRomEn]==0    <b>SPIx00</b> [SpiHostAccessRomEn]==0) THEN Read-only. ELSE Read-write. ENDIF. Reset: 20h. Same as MacLockCmd0.                                                                                                                                                                                                                                                                                                                                     |
| 7:0   | <b>MacLockCmd0.</b> IF ( <b>SPIx00</b> [SpiAccessMacRomEn]==0    <b>SPIx00</b> [SpiHostAccessRomEn]==0) THEN Read-only. ELSE Read-write. ENDIF. Reset: 6h. This is used to compare against the opcode sent out by the MAC. If <b>SPIx0C</b> [TrackMacLockEn]==1, the controller locks the SPI bus for the MAC. In other words, the MAC has the exclusive access to the ROM and access by the CPU is delayed until this is unlocked. This allows the MAC to do a certain sequence of operations without interruption. |

| 7:0  | <b>SPI_ExtReg_Data.</b> Read-write. Reset: 0. Specifies the read data or write data of the extended SPI register. |

**SPIx1F\_x00 DDR\_CMD**

| Bits | Description                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DDR_CMD.</b> Read-write. Reset: 3Bh. Specifies the command value to be used when host is doing a Dual Output Read. |

**SPIx1F\_x01 QDR\_CMD**

| Bits | Description                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>QDR_CMD</b> . Read-write. Reset: 6Bh. Specifies the command value to be used when host is doing a Quad Output Read. |

**SPIx1F\_x02 DPR\_CMD**

| Bits | Description                                                                                                                         |
|------|-------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DPR_CMD</b> . Read-write. Reset: BBh. Specifies the command value to be used when host is doing a Dual IO High Performance Read. |

**SPIx1F\_x03 QPR\_CMD**

| Bits | Description                                                                                                                         |
|------|-------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>QPR_CMD</b> . Read-write. Reset: EBh. Specifies the command value to be used when host is doing a Quad IO High Performance Read. |

**SPIx1F\_x04 ModeByte**

| Bits | Description                             |
|------|-----------------------------------------|
| 7:0  | <b>ModeByte</b> . Read-write. Reset: 0. |

**SPIx1F\_x05 TxByteCount**

| Bits | Description                                                                                     |
|------|-------------------------------------------------------------------------------------------------|
| 7:0  | <b>TxByteCount</b> . Read-write. Reset: 0. Specifies the number of bytes to be sent to SPI ROM. |

**SPIx1F\_x06 RxByteCount**

| Bits | Description                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------|
| 7:0  | <b>RxByteCount</b> . Read-write. Reset: 0. Specifies the number of bytes to be received from the SPI ROM. |

**SPIx1F\_x07 SPIDataFifoPtr**

| Bits | Description                                                                                         |
|------|-----------------------------------------------------------------------------------------------------|
| 7:0  | <b>SPiDataFiFoPtr</b> . Read-only. Reset: 0. Specifies the current pointer of read/write Data FIFO. |

**SPIx20 SPI100 Enable**

| Bits | Description                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**SPIx2C SPI100 Host Prefetch Config**

Whenever there is read from host, we will start to prefetch ROM data into the Host Prefetch Buffer. The

prefetch will start from the first address requested by host, and finish when any of the following happens:

- We have reached the maximum prefetch size defined in HostPrefetchSize and HostPrefOn64ByteBoundary register.
- When host requests an address that is not already prefetched and not going to be prefetched shortly, we stop current prefetch action and re-start a new prefetch with the first address being the current address requested by Host.
- When there is a ROM-Write or AltOpCode request from host, the on-going prefetch will be terminated, and the prefetch buffer will be flushed.
- When there is a TPM-Write, TPM-Read, USB-Read or EC-Read request, the on-going prefetch will be halted. The contents of prefetch buffer will be preserved so that host can access them later.

There are two prefetch prediction algorithms selected by HostWillHitEn and HostHitSoonEn:

- "Will Hit" algorithm. The current requested address will be fetched "shortly" if this equation is true: Current Requested Address  $\leq$  (First Prefetched Address + HostPrefetchSize).
- "Hit Soon" algorithm. The current requested address will be fetched "shortly" if this equation is true: Current Requested Address  $\leq$  (Last Prefetched Address + HostHitRange).

Of course, the current requested address also has to be equal to or larger than the first prefetched address. If current requested address meet the criteria, the on-going prefetch continues and host waits until the prefetch buffer receives the requested data.

| Bits | Description                                                                                                                                                                                                                                                                                                                      |

| 7:0   | <b>DoneByteCount</b> . Read-only; updated-by-hardware. Reset: 0. Indicates how many bytes has been received or sent in the previous SPI transaction. |

**SPIx[C6:80] FIFO[70:0]**

| Bits | Description                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>FiFo</b> . Read-write. Reset: 0. Contains the Data FiFo byte which is used in command mode to send or receive data. |

**3.26.10 High Precision Event Timer (HPET) Registers**

HPET registers are accessed through two methods:

- Memory access to HPET memory address range from FED0\_0000h to FED0\_01FFh. Program [PMx00](#)[HpetEn]=1 to enable HPET decoding.
- Memory mapped access through the AcpiMmio region. The HPET registers range from FED8\_0000h+C00h to FED8\_0000h+CFFh. See [PMx04](#)[MmioEn].

**HPETx000 ID**

| Bits  | Description                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>VendorID</b> . Read-only. Reset: 1022h.                                                                   |
| 15    | <b>LegacyCap</b> . Read-only. Reset: 1. Legacy replacement interrupt is supported.                           |
| 14    | Reserved.                                                                                                    |
| 13    | <b>CounterSizeCap</b> . Read-only. Reset: 0. Main counter is 32-bits wide and cannot operate in 64-bit mode. |
| 12:8  | <b>NumTmrCap</b> . Read-only. Reset: 02h. Three timers are supported.                                        |
| 7:0   | <b>RevID</b> . Read-only. Reset: 01h. Revision ID.                                                           |

**HPETx004 ClkPeriod**

| Bits | Description                                                                                                                                                                                                                                                                                          |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>CounterClkPeriod</b> . Read-only; updated-by-hardware. Reset: 0429_B17Eh. Specifies the clock period of each HPET timer tick. HPET main counter runs at 14.31818 MHz. The unit is femtosecond ( $10^{-15}$ seconds). The value of this register can be modified through <a href="#">MISCx74</a> . |

**HPETx010 Config**

| Bits | Description                                                                                                                                                                 |

**HPETx1[4:0:Step2]8 Timer[2:0] Comparator**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | <b>ComparatorHi</b> . Read-write. IF (PMx00[HpetWidthSel]==1) THEN Reset: FFFF_FFFFh. ELSE Reset: 0000_0000h. ENDIF. Specifies the upper 32 bits of the 64-bit timer comparator. Bits [31:0] contain the lower 32 bits of the 64-bit timer comparator.                                                                                                                                                                                                           |
| 31:0  | <b>Comparator</b> . IF (HPETx1[4:0:Step2]0[TmrTyp] == 0) THEN Read-write. ELSEIF ((HPETx1[4:0:Step2]0[TmrTyp] == 1) && (HPETx1[4:0:Step2]0[TmrSetPer] == 1)) THEN Read-write. ELSE Read-only. ENDIF. Reset: FFFF_FFFFh. Comparator is periodically incremented by the value last written to this register. This register is updated by hardware when (HPETx1[4:0:Step2]0[TmrTyp] == 1) && the current value in this register matches with the value in HPETx0F0. |

**HPETx1[5:1:step2]0 Timer[2:0] FSB Interrupt Data**

| Bits | Description                                                                                                                                              |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>TnFsbIntVal</b> . Read-write. Reset: 0000_0000h. Software sets this 32-bit field to specify the write data of Front Side Bus (FSB) Interrupt Message. |

**HPETx1[5:1:step2]4 Timer[2:0] FSB Interrupt Address**

| Bits | Description                                                                                                                                            |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>TnFsbIntAddr</b> . Read-write. Reset: 0000_0000h. Software sets this 32-bit field to specify the address of Front Side Bus (FSB) Interrupt Message. |

**HPETx1[D:B]0 Timer[2:0] Comparator Base Shadow**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                              |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | <b>TmrCompBaseShadowHi</b> . Read-write. IF (PMx00[HpetWidthSel]==1) THEN Reset: FFFF_FFFFh. ELSE Reset: 0000_0000h. ENDIF. This is shadow of the base value of HPETx1[4:0:Step2]8[ComparatorHi]. Reading this register returns the base value of HPETx1[4:0:Step2]8[ComparatorHi]. Writing the register will change the base value of HPETx1[4:0:Step2]8[ComparatorHi]. |
| 31:0  | <b>TmrCompBaseShadowLo</b> . Read-write. Reset: FFFF_FFFFh. This is shadow of the base value of HPETx1[4:0:Step2]8[Comparator]. Reading this register returns the base value of HPETx1[4:0:Step2]8[Comparator]. Writing the register will change the base value of HPETx1[4:0:Step2]8[Comparator].                                                                       |

**HPETx1[D:B]8 Timer[2:0] Comparator Shadow**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | <b>TmrCompShadowHi.</b> Read-write. IF ( <b>PMx00</b> [HpetWidthSel]==1) THEN Reset: FFFF_FFFFh. ELSE Reset: 0000_0000h. ENDIF. This is shadow of the current value of <b>HPETx1[4:0:Step2]8</b> [ComparatorHi]. Reading this register returns the current value of <b>HPETx1[4:0:Step2]8</b> [ComparatorHi]. Writing the register will change the current value of <b>HPETx1[4:0:Step2]8</b> [ComparatorHi]. |
| 31:0  | <b>TmrCompShadowLo.</b> Read-write. Reset: FFFF_FFFFh. This is shadow of the current value of <b>HPETx1[4:0:Step2]8</b> [Comparator]. Reading this register returns the current value of <b>HPETx1[4:0:Step2]8</b> [Comparator]. Writing the register will change the current value of <b>HPETx1[4:0:Step2]8</b> [Comparator].                                                                                |

**HPETx1E0 Main Counter RTC**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | <b>MainCounterRtcHi.</b> Read-write. Reset: 0000_0000. IF ( <b>PMx00</b> [HpetWidthSel]==1) THEN Specifies the shadow of <b>HPETx0F0</b> [MainCounterHi]. See <b>MainCounterRtcLo</b> . ELSE Reserved. ENDIF.                                                                                                                                                                                                                                                                                   |
| 31:0  | <b>MainCounterRtcLo.</b> Read-write. Reset: 0000_0000. This is a shadow of <b>HPETx0F0</b> [MainCounter]. It samples the value of Main Counter at every falling edge of RTC 32 KHz clock for software to read. When software writes this register, <b>HPETx0F0</b> [MainCounter] will be updated with the same value written to this register, and then enabled counting at the next RTC clock falling edge. The purpose of this register is for the convenience of software save/restore HPET. |

**HPETx1E8 Next Timer Remain**

| Bits  | Description                                                                                                                                                                                                                 |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | <b>NxtTmrRemainHi.</b> Read-write. Reset: 0000_0000. IF ( <b>PMx00</b> [HpetWidthSel]==1) THEN Specifies the upper 32 bits of the timer ticks remaining before the next enabled comparator interrupt. ELSE Reserved. ENDIF. |
| 31:0  | <b>NxtTmrRemainLo.</b> Read-only. Reset: FFFF_FFFFh. Specifies how many timer ticks remaining before the next enabled comparator interrupt.                                                                                 |

**3.26.11 Miscellaneous (MISC) Registers**

MISC register space is accessed through the AcpiMmio region. The MISC registers range from FED8\_0000h+E00h to FED8\_0000h+EFFh. See [PMx04\[Mmio\]](#).

**MISCx00 GPPClkCtrl**

BIOS: See [2.17.9.1](#).

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |      |            |       |      |       |            |       |            |       |            |       |            |             |                |       |              |             |                |       |     |

| 15:12       | <p><b>GPP_CLK3_ClockRequestMapping</b>. Read-write. Reset: Fh. GPP3 PCIe clock pins (GPP_CLK3P/GPP_CLK3N) output control by CLK_REQ# pin. GPP_CLK3P/GPP_CLK3N pins are powered off when FCH is strapped to use an external clock, and powered on when FCH is strapped to operate in integrated clock mode. When FCH is in integrated clock mode, GPP3 PCIe clock can be powered off according to the CLK_REQ mapping table below, and the selected CLK_REQ# input can power off the GPP3 PCIe clock output pins if it is asserted.</p> <p>GPP3_CLKREQ_Mapping:</p> <table> <tr> <th>Bits</th><th>Definition</th></tr> <tr> <td>0000b</td><td>Off.</td></tr> <tr> <td>0001b</td><td>CLK_REQ0#.</td></tr> <tr> <td>0010b</td><td>CLK_REQ1#.</td></tr> <tr> <td>0011b</td><td>CLK_REQ2#.</td></tr> <tr> <td>0100b</td><td>CLK_REQ3#.</td></tr> <tr> <td>1001b-0101b</td><td>Reserved; Off.</td></tr> <tr> <td>1010b</td><td>CLK_REQGfx#.</td></tr> <tr> <td>1110b-1011b</td><td>Reserved; Off.</td></tr> <tr> <td>1111b</td><td>On.</td></tr> </table> | Bits | Definition | 0000b | Off. | 0001b | CLK_REQ0#. | 0010b | CLK_REQ1#. | 0011b | CLK_REQ2#. | 0100b | CLK_REQ3#. | 1001b-0101b | Reserved; Off. | 1010b | CLK_REQGfx#. | 1110b-1011b | Reserved; Off. | 1111b | On. |

| 11:8        | <p><b>GPP_CLK2_ClockRequestMapping.</b> Read-write. Reset: Fh. GPP2 PCIe clock pins (GPP_CLK2P/GPP_CLK2N) output control by CLK_REQ# pin. GPP_CLK2P/GPP_CLK2N pins are powered off when FCH is strapped to use an external clock, and powered on when FCH is strapped to operate in integrated clock mode. When FCH is in integrated clock mode, GPP2 PCIe clock can be powered off according to the CLK_REQ mapping table below, and the selected CLK_REQ# input can power off the GPP2 PCIe clock output pins if it is asserted.</p> <p>GPP2_CLKREQ_Mapping:</p> <table> <tr> <th><u>Bits</u></th><th><u>Definition</u></th></tr> <tr> <td>0000b</td><td>Off.</td></tr> <tr> <td>0001b</td><td>CLK_REQ0#.</td></tr> <tr> <td>0010b</td><td>CLK_REQ1#.</td></tr> <tr> <td>0011b</td><td>CLK_REQ2#.</td></tr> <tr> <td>0100b</td><td>CLK_REQ3#.</td></tr> <tr> <td>1001b-0101b</td><td>Reserved; Off.</td></tr> <tr> <td>1010b</td><td>CLK_REQGfx#.</td></tr> <tr> <td>1110b-1011b</td><td>Reserved; Off.</td></tr> <tr> <td>1111b</td><td>On.</td></tr> </table> | <u>Bits</u> | <u>Definition</u> | 0000b | Off. | 0001b | CLK_REQ0#. | 0010b | CLK_REQ1#. | 0011b | CLK_REQ2#. | 0100b | CLK_REQ3#. | 1001b-0101b | Reserved; Off. | 1010b | CLK_REQGfx#. | 1110b-1011b | Reserved; Off. | 1111b | On. |

| 7:4         | <p><b>GPP_CLK1_ClockRequestMapping.</b> Read-write. Reset: Fh. GPP1 PCIe clock pins (GPP_CLK1P/GPP_CLK1N) output control by CLK_REQ# pin. GPP_CLK1P/GPP_CLK1N pins are powered off when FCH is strapped to use an external clock and powered on when FCH is strapped to operate in integrated clock mode. When FCH is in integrated clock mode, GPP1 PCIe clock can be powered off according to the CLK_REQ mapping table below, and the selected CLK_REQ# input can power off GPP1 PCIe clock output pins if it is asserted.</p> <p>GPP1_CLKREQ_Mapping:</p> <table> <tr> <th><u>Bits</u></th><th><u>Definition</u></th></tr> <tr> <td>0000b</td><td>Off.</td></tr> <tr> <td>0001b</td><td>CLK_REQ0#.</td></tr> <tr> <td>0010b</td><td>CLK_REQ1#.</td></tr> <tr> <td>0011b</td><td>CLK_REQ2#.</td></tr> <tr> <td>0100b</td><td>CLK_REQ3#.</td></tr> <tr> <td>1001b-0101b</td><td>Reserved; Off.</td></tr> <tr> <td>1010b</td><td>CLK_REQGfx#.</td></tr> <tr> <td>1110b-1011b</td><td>Reserved; Off.</td></tr> <tr> <td>1111b</td><td>On.</td></tr> </table>     | <u>Bits</u> | <u>Definition</u> | 0000b | Off. | 0001b | CLK_REQ0#. | 0010b | CLK_REQ1#. | 0011b | CLK_REQ2#. | 0100b | CLK_REQ3#. | 1001b-0101b | Reserved; Off. | 1010b | CLK_REQGfx#. | 1110b-1011b | Reserved; Off. | 1111b | On. |

| 3:0         | <p><b>GPP_CLK0_ClockRequestMapping.</b> Read-write. Reset: Fh. GPP0 PCIe clock pins (GPP_CLK0P/GPP_CLK0N) output control by CLK_REQ# pin. GPP_CLK0P/GPP_CLK0N pins are powered off when FCH is strapped to use an external clock and powered on when FCH is strapped to operate in integrated clock mode. When FCH is in integrated clock mode, GPP0 PCIe clock can be powered off according to the CLK_REQ mapping table below, and the selected CLK_REQ# input can power off the GPP0 PCIe clock output pins if it is asserted.</p> <p>GPP0_CLKREQ_Mapping:</p> <table> <tr> <th><u>Bits</u></th><th><u>Definition</u></th></tr> <tr> <td>0000b</td><td>Off.</td></tr> <tr> <td>0001b</td><td>CLK_REQ0#.</td></tr> <tr> <td>0010b</td><td>CLK_REQ1#.</td></tr> <tr> <td>0011b</td><td>CLK_REQ2#.</td></tr> <tr> <td>0100b</td><td>CLK_REQ3#.</td></tr> <tr> <td>1001b-0101b</td><td>Reserved; Off.</td></tr> <tr> <td>1010b</td><td>CLK_REQGfx#.</td></tr> <tr> <td>1110b-1011b</td><td>Reserved; Off.</td></tr> <tr> <td>1111b</td><td>On.</td></tr> </table> | <u>Bits</u> | <u>Definition</u> | 0000b | Off. | 0001b | CLK_REQ0#. | 0010b | CLK_REQ1#. | 0011b | CLK_REQ2#. | 0100b | CLK_REQ3#. | 1001b-0101b | Reserved; Off. | 1010b | CLK_REQGfx#. | 1110b-1011b | Reserved; Off. | 1111b | On. |

| 26    | <b>EXT_CLK_ClockSourceOverride.</b> Read-write. Reset: 0. EXT_CLK clock source override control. EXT_CLK clock source is controlled by strap (LPCCLK1). If Strap (LPCCLK1) == 1, clock source is from CG_PLL. If Strap (LPCCLK1) == 0, clock source is from external clock chip through GPP_CLK3_P/N pins. This override bit allows to invert the strap that controls EXT_CLK clock source. 0=Use the strap value (LPCCLK1) to determine whether EXT_CLK clock source from either CG_PLL or external clock chip. 1=Invert the strap that controls EXT_CLK clock source.                                                                                                                                                                                                              |      |            |     |                                                           |     |                                               |     |                                                  |     |                                                  |

| 12    | <b>GFX_GPP_CLK_ClockOutputOverride: GFX_GPP_CLK [2:0] ClockOutputOverride.</b> Read-write. Reset: 0. GFX_GPP_CLK[2:0] clock output override control. GFX_CLK and GPP_CLK[2:0] clock outputs are controlled by [SLT_GFX_CLKClockRequestMapping] and <a href="#">MISCx00[GPP_CLK0_ClockRequestMapping, GPP_CLK1_ClockRequestMapping, GPP_CLK2_ClockRequestMapping]</a> . Basically it depends on whether chip is in internal (Strap (LPCCLK1) == 1) or external (Strap (LPCCLK1) == 0) clock mode. This override bit allows to invert the strap value that controls clock output buffer. 0=Use SLT_GFX Clock Request mapping and GPP_CLK[2:0] Clock Request mapping to determine whether clock output buffer is on or off. 1=Invert the strap that controls those clock output buffer. |      |            |     |                                                           |     |                                               |     |                                                  |     |                                                  |
| 11    | <b>GPP_CLK3_ClockOutputOverride.</b> Read-write. Reset: 0. GPP_CLK3 clock output override control. GPP_CLK3 is a bi-directional pin depending on LPCCLK1 strap value. If Strap (LPCCLK1) == 1, GPP_CLK3 provides clock for external device and output buffer will be on. If Strap (LPCCLK1) == 0, GPP_CLK3 receives clock from external clock chip and output buffer will be off. This override bit allows to invert the strap that controls GPP_CLK3 clock output buffer. 0=Use the strap value (LPCCLK1) to determine whether GPP_CLK3 clock output buffer is on or off. 1=Invert the strap that controls GPP_CLK3 clock output buffer.                                                                                                                                            |      |            |     |                                                           |     |                                               |     |                                                  |     |                                                  |

| 10          | <b>CPU_CLK_ClockSourceOverride.</b> Read-write. Reset: 0. CPU_CLK clock source override control. CPU_CLK clock source is controlled by strap (LPCCLK1). If Strap (LPCCLK1)==1, CPU_CLK clock source is from CG_PLL. If Strap (LPCCLK1)==0, CPU_CLK clock source is from external clock chip through GPP_CLK3_P/N pins. This override bit allows to invert the strap that controls CPU_CLK clock source. 0=Use the strap value (LPCCLK1) to determine whether CPU_CLK clock source from either CG_PLL or external clock chip. 1=Invert the strap that controls CPU_CLK clock source.                                                                                                                                                                                                                                                                                                                                                                                                                                                |      |            |       |                             |       |                             |       |                            |       |            |       |            |             |                |       |              |             |                |       |     |

| 7:4         | <b>SLT_GFX_CLK_ClockRequestMapping.</b> Read-write. Reset: Fh. Gfx PCIe clock pins (SLT_GFX_CLKP/SLT_GFX_CLKN) output control. SLT_GFX_CLKP/SLT_GFX_CLKN pins are powered off when FCH is strapped to use an external clock, and powered on when FCH is strapped to operate in integrated clock mode. When FCH is in integrated clock mode, Gfx PCIe clock can be powered off according to the CLK_REQ mapping table below, and the selected CLK_REQ# input can power off Gfx PCIe clock output pins if it is asserted.<br>Gfx_CLKREQ_Mapping:<br><table> <tr> <th>Bits</th><th>Definition</th></tr> <tr> <td>0000b</td><td>Off.</td></tr> <tr> <td>0001b</td><td>CLK_REQ0#.</td></tr> <tr> <td>0010b</td><td>CLK_REQ1#.</td></tr> <tr> <td>0011b</td><td>CLK_REQ2#.</td></tr> <tr> <td>0100b</td><td>CLK_REQ3#.</td></tr> <tr> <td>1001b-0101b</td><td>Reserved; Off.</td></tr> <tr> <td>1010b</td><td>CLK_REQGfx#.</td></tr> <tr> <td>1110b-1011b</td><td>Reserved; Off.</td></tr> <tr> <td>1111b</td><td>On.</td></tr> </table> | Bits | Definition | 0000b | Off.                        | 0001b | CLK_REQ0#.                  | 0010b | CLK_REQ1#.                 | 0011b | CLK_REQ2#. | 0100b | CLK_REQ3#. | 1001b-0101b | Reserved; Off. | 1010b | CLK_REQGfx#. | 1110b-1011b | Reserved; Off. | 1111b | On. |

**3.26.12 GPIO Pin control registers**

The GPIO pins are controlled by a combination of device enables and by their specific GPIO and IOMUX register pair.

**3.26.12.1 GPIO Registers**

GPIO registers are accessed through memory-mapped ACPIMMIO region. The offset is relative to FED8\_0000h+1500h. GPIO bank 0 registers range from FED8\_0000h+1500h to FED8\_0000h+15FFh. GPIO Bank 1 registers range from FED8\_0000h+1600h to FED8\_0000h+16FFh. GPIO Bank 2 registers range from FED8\_0000h+1700h to FED8\_0000h+17FFh.

**GPIOx[0F8:000:step4] GPIO Bank 0 Control Register**

Each GPIO pin is controlled by 4 bytes. These registers control GPIO bank 0 pins: GPIO62-GPIO00.

Table 265: Function name for [GPIOx\[0F8:000:step4\]](#)

| Register | Reset      | Function           | Register | Reset      | Function           |

### GPIOx[1FC:100:step4] GPIO Bank 1 Control Register

Each GPIO pin is controlled by 4 bytes. These registers control GPIO bank 1 pins: GPIO64-GPIO127.

Table 267: Function name for [GPIOx\[1FC:100:step4\]](#)

| Register | Reset      | Function         | Register | Reset      | Function             |

**GPIOx[2DC:200:step4] GPIO Bank 2 Control Register**

Each GPIO pin is controlled by 4 bytes. These registers control GPIO Bank 2 pins: GPIO128-GPIO183.

Table 268: Function name for [GPIOx\[2DC:200:step4\]](#)

| Register | Reset      | Function                | Register | Reset      | Function                  |

### 3.26.13 Power Management (PM) Registers

PM register space is accessed through two methods:

- Indirect IO access through [IOCD6 \[PM\\_Index\]](#) and [IOCD7 \[PM\\_Data\]](#). Software first programs the offset into the index register [IOCD6](#) and then reads from or writes to the data register [IOCD7](#).
- Direct memory mapped access through the AcpiMmio region. The PM registers range from FED8\_0000h+300h to FED8\_0000h+3FFh. See [PMx04\[MmioEn\]](#) for details on the AcpiMmio region.

| 4:0  | <b>FallBackMonth.</b> Read-write. Reset: 0. This Binary-Coded Decimal (BCD) value specifies which month to “fall back”. |

**PMx5F\_x10 RTCEXT WeekTimerControl**

The 16-bit Week Timer is a battery-powered down counter timer that supports 1ms, 1 second, and 1minute resolution and auto reloads when the timer reaches 0. The WEEK\_ALRM interrupt is asserted when the timer reaches 0 and stays asserted until the timer is disabled.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |      |            |      |            |     |          |     |      |     |          |     |          |

| 111b  | If CPU is in C-state and the controller has already exhausted the link list, it can simply stop the asynchronous packets until CPU resumes back to C0 state. In this case, the controller will resume back to its standard mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |      |            |      |                       |      |                                          |      |                                          |      |                                          |      |                                            |      |           |      |           |      |                                                                                                                                                                                                                                  |

### 3.26.14 Power Management Block 2 (PM2) Registers

PM2 register space is accessed through two methods:

- Indirect IO access through index/data address pair at [IOCD0 \[PM2\\_Index\]](#) and [IOCD1 \[PM2\\_Data\]](#). Software first programs the offset into the index register [IOCD0 \[PM2\\_Index\]](#) and then reads/writes to/from the data register [IOCD1 \[PM2\\_Data\]](#).
- Memory mapped access through the AcpiMmio region. The ACPI registers range from FED8\_0000h+400h to FED8\_0000h+4FFh. See [PMx04\[MmioEn\]](#) for details on the AcpiMmio region.

#### PM2x01 Fan0Control

When [AutoMode] == 1, the active duty cycle is controlled by the hardware automatically.

- If ActualTemperature < LowTemp{[PM2x07](#), [PM2x06](#)}, DutyCycle = 0.
- If LowTemp{[PM2x07](#), [PM2x06](#)} <= ActualTemperature < MedTemp{[PM2x09](#), [PM2x08](#)}, DutyCycle = [PM2x03 \[LowDuty0\]](#).
- If MedTemp{[PM2x09](#), [PM2x08](#)} <= ActualTemperature < HighTemp{[PM2x0B](#), [PM2x0A](#)}:
  - If [LinearMode] == 0, DutyCycle = [PM2x04 \[MedDuty0\]](#).
  - If [LinearMode] == 1, DutyCycle = ((ActualTemperature - LowTemp{[PM2x07](#), [PM2x06](#)}) \* ([PM2x05\[Multiplier\]](#) + 1) >> [PM2x05\[DutySel\]](#)) + [PM2x03 \[LowDuty0\]](#).
- If ActualTemperature >= HighTemp{[PM2x0B](#), [PM2x0A](#)}, DutyCycle = 100%.

In Automode, hysteresis limit defined by [PM2x0C \[LinearRange0\]](#) is applied to keep the fan from oscillating erratically.

| FFh     | Full speed run.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |      |            |     |              |         |                                                                      |     |                 |

**PM2x05 Multiplier0**

When (PM2x01[AutoMode] == 1) && (PM2x00[TwoRampAlgorithm] == 1), Fan0 is in TwoRamp mode. The slope value of ramp1 and ramp0 is: Slope[7:0] = {PM2x05[DutySel], PM2x05[Multiplier]}. Slope[7:2] are the integer bits and Slope[1:0] are the fractional bits of the ramp slope.

BIOS has to calculate Slope[7:0] using the following equation:

$$\text{Slope} = (\text{FF00h} - \{\text{LowDuty0}[7:0], 0000\_0000\text{b}\}) / (\text{HighTemp0}[15:0] - \text{Hysteresis0}[15:0] - \text{MedTemp0}[15:0])$$

For example, if our setting is:

LowDuty0[7:0] = 25% = 40h

HighTemp0[15:0] = 90°C = 5A00h

MedTemp0[15:0] = 40°C = 2800h

Hysteresis0[15:0] = 10°C = 0A00h

Then:

Slope = (FF00h - 4000h) / (5A00h - 0A00h - 2800h) = 48896 / 10240 = 4.775.

Convert the number 4.775 into our 8-bit format: 0001\_0011b (13h). BIOS should program the Multiplier0 register as 13h in this example.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:6  | <b>DutySel.</b> Read-write. Reset: 0. When Fan0 is programmed in AutoMode with linear function being selected, this field selects part of duty to be fed into fan as described in <a href="#">PM2x01 [Fan0Control]</a> register description. When Fan0 is programmed in TwoRamp mode, this field specifies the upper 2 bits in Slope[7:0]. See the above register description for detail.          |
| 5:0  | <b>Multiplier.</b> Read-write. Reset: 0. When Fan0 is programmed in AutoMode with linear function being selected, this field specifies the factor to calculate duty number as described in <a href="#">PM2x01 [Fan0Control]</a> register description. When Fan0 is programmed in TwoRamp mode, this field specifies the lower 6 bits in Slope[7:0]. See the above register description for detail. |

#### PM2x06 LowTemp0Lo

| Bits | Description                                                                                          |
|------|------------------------------------------------------------------------------------------------------|
| 7:0  | <b>LowTemp0[7:0].</b> Read-write. Reset: 0. Specifies the lower 8 bits of low temperature threshold. |

#### PM2x07 LowTemp0Hi

| Bits | Description                                                                                            |
|------|--------------------------------------------------------------------------------------------------------|
| 7:0  | <b>LowTemp0[15:8].</b> Read-write. Reset: 0. Specifies the higher 8 bits of low temperature threshold. |

#### PM2x08 MedTemp0Lo

| Bits | Description                                                                                             |
|------|---------------------------------------------------------------------------------------------------------|
| 7:0  | <b>MedTemp0[7:0].</b> Read-write. Reset: 0. Specifies the lower 8 bits of medium temperature threshold. |

#### PM2x09 MedTemp0Hi

| Bits | Description                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------|
| 7:0  | <b>MedTemp0[15:8].</b> Read-write. Reset: 0. Specifies the higher 8 bits of medium temperature threshold. |

#### PM2x0A HighTemp0Lo

| Bits | Description                                                                                            |
|------|--------------------------------------------------------------------------------------------------------|
| 7:0  | <b>HighTemp0[7:0].</b> Read-write. Reset: 0. Specifies the lower 8 bits of high temperature threshold. |

**PM2x0B HighTemp0Hi**

| Bits | Description                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------|
| 7:0  | <b>HighTemp0[15:8]</b> . Read-write. Reset: 0. Specifies the higher 8 bits of high temperature threshold. |

**PM2x0C LinearRange0**

| Bits | Description                                                                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>LinearRange</b> . Read-write. Reset: 0. Specifies a variable range that Fan0 can tolerate. Fan0 is not affected if temperature varies within this range. |

**PM2x0D LinearHoldCount0**

| Bits | Description                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>LinearHoldCount</b> . Read-write. Reset: 0. Specifies the fan cycles to be waited before duty cycle can be changed. |

**PM2x0E Fan0Hysteresis**

| Bits | Description                                                                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8 | <b>HysteresisHi</b> . Read-write. Reset: 0. Specifies the hysteresis value (in temperature) of the Two Ramp Fan Control Algorithm. The unit is °C. See <a href="#">PM2x05 [Multiplier0]</a> on how to program this register. |
| 7:0  | <b>HysteresisLo</b> . Read-write. Reset: 0. This byte should always be programmed as 0.                                                                                                                                      |

| Bits | Description                                                                                                                                                                                                        |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Med2Temp0[7:0]</b> . Read-write. Reset: 0. IF ( <a href="#">PM2x00[TwoRampAlgorithmEn]</a> ==1) THEN It specifies the lower byte of the temperature value of the turning point on the ramp. ELSE Unused. ENDIF. |

**PM2x51 Med2Temp0Hi**

| Bits | Description                                                                                                                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Med2Temp0[15:8]</b> . Read-write. Reset: 0. IF ( <a href="#">PM2x00[TwoRampAlgorithmEn]</a> ==1) THEN It specifies the higher byte of the temperature value of the turning point on the ramp. ELSE Unused. ENDIF. |

**PM2x52 Med2Duty0**

| Bits | Description                                                                                                                                                                                   |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Med2Duty0[7:0]</b> . Read-write. Reset: 0. IF ( <a href="#">PM2x00[TwoRampAlgorithmEn]</a> ==1) THEN It specifies the fan duty value of the turning point on the ramp. ELSE Unused. ENDIF. |

**PM2x53 Multiplier2\_0**

BIOS has to calculate Multiplier2\_0[7:0] using the following equation:

$\text{Multiplier2\_0} = (\{\text{Med2Duty0}[7:0], 0000\_0000b\} - \{\text{LowDuty0}[7:0], 0000\_0000b\}) / (\text{Med2Temp0}[15:0] - \text{MedTemp0}[15:0])$ .

For example, if our setting is:

**PM2x52**[Med2Duty0[7:0]] = 50% = 80h

**PM2x03**[LowDuty0[7:0]] = 25% = 40h

Med2Temp0[15:0] = {**PM2x51**, **PM2x50**} = 70°C = 4600h

MedTemp0[15:0] = {**PM2x09**, **PM2x08**} = 40°C = 2800h

Then:

$\text{Multiplier2\_0}[7:0] = (8000h - 4000h) / (4600h - 2800h) = 16384 / 7680 = 2.133$ .

Convert the number 4.775 into our 8bit format: 0000\_1000b (08h). BIOS should program Multiplier2\_0 register as 08h in this example.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                           |     |            |       |                                |       |                                   |

**3.26.15 Standard ACPI Registers**

These are the standard registers defined by the ACPI specification. In order to access these ACPI registers, [PMx74](#)[DecEnAcpi] must be programmed to 1. ACPI registers are accessed through two methods:

- IO mapped access through base addresses defined by [PMx60](#) through [PMx6E](#).
- Memory mapped access through the AcpiMmio region. The ACPI registers range from FED8\_0000h+800h to FED8\_0000h+8FFh. See [PMx04](#)[MmioEn] for details on the AcpiMmio region.

**3.26.15.1 AcpiPmEvtBlk**

The IO mapped base address of this register block is defined by [PMx60](#).

**3.26.15.6 AcpiGpe0Blk**

The IO mapped base address of this register block is defined by [PMx68](#).

**AcpiGpe0Blkx00 EventStatus**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>EventStatus.</b> Read; write-1-to-clear. Reset: X. Each bit represents an ACPI event status. For each bit, 1=The selected event input equals to the corresponding value in <a href="#">SMIx08 [SciTrig]</a> . Configuration for the events are located at <a href="#">SMIx08 [SciTrig]</a> through <a href="#">SMIx78 [SciMap14]</a> . The status bits are also mirrored in <a href="#">SMIx00 [Event_Status]</a> . |

**AcpiGpe0Blkx04 EventEnable**

---

| Bits | Description                                                                                                                                                                                      |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>EventEnable</b> . Read-write. Reset: 0. Each bit controls whether ACPI should generate wakeup and SCI interrupt. The enable bits are also mirrored in <a href="#">SMIx04 [Event_Enable]</a> . |

**3.26.15.7 SmiCmdBlk**

The IO mapped base address of this register block is defined by [PMx6A](#).

**SmiCmdBlkx00 SmiCmdPort**

---

| Bits | Description                                                                                                                                                                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SmiCmdPort</b> . Read-write. Reset: 0. When SMI command port is enabled, a write to this port generates SMI, NMI or IRQ3 depending on the setting of <a href="#">SMIxB0[23:22]</a> . A read from this port returns the previously written value but does not generate SMI. |

**SmiCmdBlkx01 SmiCmdStatus**

---

| Bits | Description                                                      |
|------|------------------------------------------------------------------|
| 7:0  | <b>SmiCmdStatus</b> . Read-write. Reset: 0. Used by BIOS and OS. |

### 3.26.16 SMI Registers

SMI register space is accessed through the AcpiMmio region. The SMI registers range from FED8\_0000h+200h to FED8\_0000h+2FFh. See [PMx04\[MmioEn\]](#).

#### SMIx00 Event\_Status

| Bits | Description                                                                                                                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>EventStatus.</b> Read; write-1-to-clear. Reset: X. This is a mirror register of the standard ACPI register <a href="#">AcpiGpe0Blkx00 [EventStatus]</a> . Each event status bit is set when the selected event input equals to the corresponding value in <a href="#">SMIx08 [SciTrig]</a> . |

#### SMIx04 Event\_Enable

| Bits | Description                                                                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>EventEnable.</b> Read-write. Reset: 0. This is the mirror register of the standard ACPI register <a href="#">AcpiGpe0Blkx04 [EventEnable]</a> . Each bit controls whether ACPI should generate wake up and SCI interrupt. |

#### SMIx08 SciTrig

Each bit in this register controls the way to set each corresponding bit in [SMIx00 \[Event\\_Status\]](#).

| Bits | Description                                                                                                                                              |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | <b>SciTrig31.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 31 ( <a href="#">SMIx00[31]</a> ). 0=Active low. 1=Active high. |
| 30   | <b>SciTrig30.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 30 ( <a href="#">SMIx00[30]</a> ). 0=Active low. 1=Active high. |
| 29   | <b>SciTrig29.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 29 ( <a href="#">SMIx00[29]</a> ). 0=Active low. 1=Active high. |
| 28   | <b>SciTrig28.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 28 ( <a href="#">SMIx00[28]</a> ). 0=Active low. 1=Active high. |
| 27   | <b>SciTrig27.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 27 ( <a href="#">SMIx00[27]</a> ). 0=Active low. 1=Active high. |
| 26   | <b>SciTrig26.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 26 ( <a href="#">SMIx00[26]</a> ). 0=Active low. 1=Active high. |
| 25   | <b>SciTrig25.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 25 ( <a href="#">SMIx00[25]</a> ). 0=Active low. 1=Active high. |
| 24   | <b>SciTrig24.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 24 ( <a href="#">SMIx00[24]</a> ). 0=Active low. 1=Active high. |
| 23   | <b>SciTrig23.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 23 ( <a href="#">SMIx00[23]</a> ). 0=Active low. 1=Active high. |
| 22   | <b>SciTrig22.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 22 ( <a href="#">SMIx00[22]</a> ). 0=Active low. 1=Active high. |
| 21   | <b>SciTrig21.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 21 ( <a href="#">SMIx00[21]</a> ). 0=Active low. 1=Active high. |

|    |                                                                                                                                                   |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 20 | <b>SciTrig20.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 20 ( <b>SMIx00[20]</b> ). 0=Active low. 1=Active high.   |
| 19 | <b>SciTrig19.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 19 ( <b>SMIx00[19]</b> ). 0=Active low. 1=Active high.   |
| 18 | <b>SciTrig18.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 18 ( <b>SMIx00[18]</b> ). 0=Active low. 1=Active high.   |
| 17 | <b>SciTrig17.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 17 ( <b>SMIx00[17]</b> ). 0=Active low. 1=Active high.   |
| 16 | <b>SciTrig16.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 16 ( <b>SMIx00[16]</b> ). 0=Active low. 1=Active high.   |
| 15 | <b>SciTrig15.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 15 ( <b>SMIx00[15]</b> ). 0=Active low. 1=Active high.   |
| 14 | <b>SciTrig14.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 14 ( <b>SMIx00[14]</b> ). 0=Active low. 1=Active high.   |

**SMI<sub>x</sub>10 SMI<sub>Sci</sub>Status**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>SMI<sub>Sci</sub>Status</b> . Read; write-1-to-clear. Reset: 0. Each bit indicates the corresponding SMI <sub>Sci</sub> status. The input of each bit is controlled by the corresponding SMI <sub>x</sub> 08 [SciTrig] bit. Note: this function can be considered as a superset of SMI <sub>x</sub> 00 [Event_Status]. When one of the bits is set and its SMI <sub>x</sub> 14 [SMI <sub>Sci</sub> En] is also set, it triggers a SMI to call the BIOS. After the BIOS has serviced the SMM and cleared its status, the internal logic automatically sets the corresponding SMI <sub>x</sub> 00 [Event_Status] bit and thereby triggering a SCI. |

**SMI<sub>x</sub>14 SMI<sub>Sci</sub>En**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                               |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>SMI<sub>Sci</sub>En</b> . Read-write. Reset: 0. Each bit controls if SMI message is generated when the corresponding SMI <sub>x</sub> 10 [SMI <sub>Sci</sub> Status] bit is set to 1. For each bit, 0=Not to send SMI message when the corresponding SMI <sub>x</sub> 10 [SMI <sub>Sci</sub> Status] bit is set. 1=Send SMI message when the corresponding SMI <sub>x</sub> 10 [SMI <sub>Sci</sub> Status] bit is set. |

**SMI<sub>x</sub>18 SwSciEn**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>SwSciEn</b> . Read-write. Reset: 0. This register is used as a software mechanism to trigger SCI. For each bit, 1=Software can write to SMI <sub>x</sub> 1C [SwSciData] and set the corresponding SMI <sub>x</sub> 00 [Event_Status] bit. Note: the setting of this bit needs to match with SMI <sub>x</sub> 08 [SciTrig] and SMI <sub>x</sub> 0C [SciLevl] in order to set the status bit. |

**SMI<sub>x</sub>1C SwSciData**

| Bits | Description                                                                                                                                                                        |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>SwSciData</b> . Read-write. Reset: 0. This is the software data path to set the corresponding SMI <sub>x</sub> 00 [Event_Status] bit when SMI <sub>x</sub> 18 [SwSciEn] is set. |

**SMI<sub>x</sub>20 SciSleepDisable**

| Bits | Description                                                                                                                                                                                                                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>SciSleepDisable</b> . Read-write. Reset: 0. This register is used to ignore EVENT pins that are powered in the main power domain instead of auxiliary power domain. For each bit, 1=The corresponding SMI <sub>x</sub> 00 [Event_Status] bit is masked off whenever the system goes to S3 or higher sleep state. |

**SMI<sub>x</sub>30 CapturedData**

| Bits | Description                                                                                                                                                                        |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>CapturedData</b> . Read-only. Reset: X. This is the buffer to capture write data for the last transaction that caused an SMI. Note: this buffer has no meaning for a read trap. |

**SMI<sub>x</sub>34 CapturedValid**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                    |     |            |     |        |     |        |     |        |     |        |

### SMIx94 SmiPointer

This register is meant as a faster mechanism to locate the SMI source. BIOS can examine this register to find out the SMI source instead of reading [SMIx80 \[SmiStatus0\]](#) through [SMIx90 \[SmiStatus4\]](#) individually.

### SMIx96 SmiTimer

There are two SMI timers: the short timer runs at 1 us unit time and the long timer runs at 1 ms unit time. This register is actually made up of two sets of registers depending on the setting of [SMIx98\[SmiTimerSel\]](#). If [SMIx98\[SmiTimerSel\]](#)==0, then [SMIx96](#) is for the short timer. If [SMIx98\[SmiTimerSel\]](#)==1, then [SMIx96](#) is for the long timer. The default setting selects this register as “SmiShortTimer”; software needs to set the “SmiTimerSel=1” to select this register as “SmiLongTimer”.

| Bits | Description                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15   | <b>TimerEn.</b> Read-write. Reset: 0. 1=Enable the SMI short Timer or long timer, which is selected by <a href="#">SMIx98[SmiTimerSel]</a> . 0=Disable. |
| 14:0 | <b>SmiTimerCount.</b> Read-write. Reset: 0. Actual timer duration = TimerTime + 1 unit.                                                                 |

### SMIx98 SmiTrig0

Bit [23:0] defines the trigger mode for 24 GEVENTS in [SMIx80\[23:0\]](#). Note these are different from [SMIx08 \[SciTrig\]](#).

| Bits | Description                                                            |
|------|------------------------------------------------------------------------|
| 31   | <b>SmiEnB.</b> Read-write. Reset: 1. 0=Enable SMI function. 1=Disable. |
| 30   | Reserved.                                                              |

|    |                                                                                                                                                                          |

| Bits | Description                                                                                                                                                                                                                           |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:2 | <b>CfgTrapping</b> . Read-write. Reset: 0. Specifies the Address[31:2] value during configure cycle which causes SMI event.                                                                                                           |
| 1    | <b>IoTrappingRw0</b> . Read-write. Reset: 0. 0=Trap on IO read access on the address specified in <a href="#">SMIxC8 [IoTrapping0]</a> . 1=Trap on IO write access on the address specified in <a href="#">SMIxC8 [IoTrapping0]</a> . |
| 0    | <b>CfgTrappingRw</b> . Read-write. Reset: 0. 0=Trap on read access at the address specified in [CfgTrapping]. 1=Trap on write access.                                                                                                 |

### 3.26.17 Watchdog Timer (WDT) Registers

Watchdog timer registers are accessed through two methods:

- Memory access to Watchdog Timer memory address range from FEB0\_0000h to FEB0\_000Fh. Program [PMx00](#)[WatchdogTmrEn]=1 to enable Watchdog Timer decoding.
- Memory mapped access through the AcpiMmio region. The Watchdog Timer registers start from FED8\_0000h+B00h. See [PMx04](#)[MmioEn].

#### WDTx00 WatchdogControl

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 7    | <b>WatchdogTrigger.</b> IF (!WatchdogDisable && WatchdogRunStopB) THEN RAZ; write-1-only. ELSE RAZ. ENDIF. Reset: 0. Writing 1 to this bit triggers the watchdog to start a new count interval, counting down from the value that was last written to <a href="#">WDTx04</a> .                                                                                                                                                                                                                                                                           |
| 6:4  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 3    | <b>WatchdogDisable.</b> Read-only. Reset: 1. This bit reflects the state of the watchdog timer hardware. 0=Enable. 1=Disable.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 2    | <b>WatchdogAction.</b> Read-write. Reset: 0. This bit determines the action to be taken when the watchdog timer expires. 0=System reset. 1=System power off. The bit is only valid when the watchdog is enabled.                                                                                                                                                                                                                                                                                                                                         |
| 1    | <b>WatchdogFired.</b> Read; write-1-to-clear. Cold reset: 0. 1=The watchdog timer has expired and caused the current restart. The bit is cleared by a power cycle or by the operating system and it must remain cleared for any restart that is not caused by the watchdog timer firing. The bit is only valid when the watchdog is enabled.                                                                                                                                                                                                             |
| 0    | <b>WatchdogRunStopB.</b> Read-write. Reset: 0. 1=Watchdog is in the running state. 0=Watchdog is in the stopped state. This bit is used to control or indicate whether the watchdog is in the running or stopped states. If the watchdog is in the stopped state and a 1 is written to this bit, the watchdog moves to the running state, but a count interval is not started until a 1 is written to WatchdogTrigger. If the watchdog is in the running state, writing 1 to this bit has no effect. The bit is only valid when the watchdog is enabled. |

#### WDTx04 WatchdogCount

| Bits  | Description                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                    |
| 15:0  | <b>WatchdogCount.</b> Read-write. Reset: X. Writing this field specifies the countdown time for the counter. |

### 3.26.18 Wake Alarm Device (AcDcTimer) Registers

The AC/DC timer registers are used to control the wake alarm device. They are accessed through the AcpiMmio region. The AC DC timer registers range from FED8\_0000h+1D00h to FED8\_0000h+1DFFh. See [PMx04](#)[MmioEn].

**AcDcTimerx00 AcTimerValue**

| Bits                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |                   |            |                                             |                       |                                                                                                                          |            |                       |

| 31:0                  | <p><b>AcExpiredTimerPolicy.</b> Read-write; updated-by-hardware. Reset: FFFF_FFFFh. When the AC timer expires, the wake signal is asserted if the current power source is AC; the wake signal is not asserted if the current power source is DC. If the power source is switched from DC to AC after the AC timer expired, we wait for the number of seconds defined in this register and then wake up the system. When the AC or DC timer generates a wake up event, this register is reset to FFFF_FFFFh by hardware.</p> <table> <tr> <th><u>Bits</u></th><th><u>Definition</u></th></tr> <tr> <td>0000_0000h</td><td>The expired AC timer wakes up the system instantly once the power source is switched to AC.</td></tr> <tr> <td>FFFF_FFFEh-0000_0001h</td><td>The value indicates the number of seconds between the time when the power is switched to AC and the time when it generates the wake-up event.</td></tr> <tr> <td>FFFF_FFFFh</td><td>Disable the AC expired timer policy.</td></tr> </table> | <u>Bits</u> | <u>Definition</u> | 0000_0000h | The expired AC timer wakes up the system instantly once the power source is switched to AC. | FFFF_FFFEh-0000_0001h | The value indicates the number of seconds between the time when the power is switched to AC and the time when it generates the wake-up event. | FFFF_FFFFh | Disable the AC expired timer policy. |

| 0     | <b>Busy.</b> Read-only; updated-by-hardware. Reset: 0h. Right after <a href="#">AcDcTimerx00 [AcTimerValue]</a> or <a href="#">AcDcTimerx10 [DcTimerValue]</a> is programed, the hardware sets this bit to 1. The hardware will clear this bit once the programming is done and the corresponding timer is started properly. Before the software writes to <a href="#">AcDcTimerx00 [AcTimerValue]</a> or <a href="#">AcDcTimerx10 [DcTimerValue]</a> , it has to read this bit and make sure it is 0. Otherwise, the hardware will just ignore the programming action from software. For the registers other than <a href="#">AcDcTimerx00 [AcTimerValue]</a> or <a href="#">AcDcTimerx10 [DcTimerValue]</a> , there is no such limitation. |

## 4 Register List

The following is a list of all storage elements, context, and registers provided in this document. Page numbers, register mnemonics, and register names are provided.

|     |                                                     |     |                                                            |
